CHOLIK, V. R.

The Change in the Supraconductive Properties of Tantalum on Saturation with Hydrogen. V. R. Golik, R. G. Lazarev, and V. I. Khotimovich. *Zh. Fiz. Khim.*, 1949, **19**, (3), 202-206, C. 166, 1950, **44**, 4742b.
(In Russian). Electrolytic hydrogenation of tantalum wire (0.15 mm. in dia.) in slightly alkaline water results in a broadening of the temp. range of supraconductive transition, increasing with the degree of hydrogenation. At any given temp. between 1.85 and 4.2° K., the electrical resistance ratio R_0/R increased with the amount of occluded hydrogen. At near saturation R_0/R increased with the amount of occluded hydrogen, or at least with hydrogen, the sample loses supraconductivity altogether, or at least does not become supraconducting down to 1.80° K. The upper limit of the transition range remains unchanged, all samples showing a distinct drop in R at that point. At const. temp. and varying magnetic field strength, H , hydrogenation again produces increasing broadening of the transition range. This broadening of the transition ranges of T and H makes the determination of the critical values T_c and H_c impossible. The linear plots of H_c against T move to increasingly lower values of T with increasing hydrogen content, with the slope dH_c/dT increasing. The amount of hydrogen occluded varies with the slope dH_c/dT increasing. Thus, if a sample, saturated with hydrogen, is heated 10 hr. at 1700° C. is cooled, its supraconductivity is suppressed after 10 hr. On repeated hydrogenation, supraconductivity is suppressed after exclusion of only 5×10^{-4} mg. of hydrogen, as against 340×10^{-4} mg. which was necessary to suppress supraconductivity originally. In contrast to tantalum, the supraconductivity of niobium is preserved at 4.2° K. after several hours' heating with hydrogen. The effect of hydrogenation on the supraconductivity of tantalum cannot be accounted for by simple expansion of the lattice, but must be due to formation of solid solution alloys.

0.15 mm. dia. wire, 14 x 0.15 x 0.15

1951
Golik, V. I.
Effect of plastic deformation on the superconductivity of metals. V. I. Khotkevich and V. R. Golik (Phys.-Tech. Inst., Acad. Sci. Ukr. S.S.R., Kiev). *Zhur. Eksp. i Teor. Fiz.* 20, 427-437 (1970). Cf. Kan, et al., C.A. 43, 4009f (1951). The wires were deformed by compression, and the ratio $r = R_0/R$ of the residual elec. resistances of the deformed

and the original sample at 4.2°K. was taken as criterion of the degree of plastic deformation, expts. with Sn wires of 0.14, 0.145, 0.10, and 0.08 mm. diam. having shown that r increases regularly with the load applied, faster with thinner wires, and reaches a satn. level with sufficiently high loads. With Sn, deformation shifts the curves of the elec. resistance R as a function of abs. temp. T to lower R at the same T , the lower the greater the load applied (0, 140, 200, and 250 kg. on a wire of 0.145 mm. diam.); increase of the plastic deformation thus results in increasing growth of the residual resistance, accompanied by increasing broadening of the range of superconductive transition. Plots of the "conventional" reduced resistance $R_r (= R \text{ at the given deformation and temp. } T \text{ and of } R \text{ of the same sample at } 4.2^\circ \text{K.})$ as a function of T , for different r , show that the crit. temp. of superconductive transition T_c first rises with increasing r up to $r \sim 7$ where it reaches a max. and then falls with further increasing r , tending to the T_c of the undeformed sample. T_c remains deformed, as usual, as the temp. at which $R_r = 0.5$, but actually the deformed samples begin to show superconductive properties at markedly higher temps. The height of the max. T_c as a function of r decreases with the diam. of the wire, but its position remains invariable. When the load corresponding to max. T_c is removed, the transition curve, instead of reverting to its original position, continues to move further to higher temps., so that T_c becomes (0.35-0.40)° higher than originally. The behavior of In is entirely analogous to that of Sn. In the case of Tl, plastic deformation results in an uninterrupted rise of T_c , reaching satn. only at very high loads, and showing only a very slight fall beyond the satn. Removal of the load again results in a further rise of T_c . The behavior of Hg is altogether different from that of Sn, In, or Tl, with T_c moving linearly to lower temps. with increasing load, and removal of the load resulting in a practically complete return of the transition curve to its original position, close to the

General and Physical Chemistry, 2

curve of undeformed Hg. (2) For Sn, In, and Hg, the temp. coeff. of the crit. magnetic field dH_c/dT increases only very slightly with the deformation, but Tl shows a strong increase, up to 300 gauss/deg., as compared with 150 for the original Tl. At the same time, the width of the transition range increases markedly (particularly with Tl attaining several tens of degrees). (3) The above effects are observed only if the plastic deformation is effected at low temps.; heating up to room temp. results in complete disappearance of all the anomalies. Compression at 77°K. does produce the anomalies but about 0.1 as large as in deformation at 4.2°K. Compression at room temp. produces no anomaly whatsoever, not even in Tl. (4) Plots of the relative shift $\Delta T_c/T_c$ as a function of r show monotonous increase for Tl, a max. for In and Sn, and monotonous decrease for Hg. The latter shows a behavior analogous to that under all-sided compression. In contrast thereto, all-sided compression of Tl is known to raise T_c , and that is observed also in plastic deformation; on the other hand, removal of the load restores the original situation after all-sided compression whereas under the same conditions T_c continues to rise after plastic deformation. With Sn and In, all-sided compression always lowers T_c , whereas plastic deformation gives a max. (5) The behavior of Sn, In, and Tl can be explained on the assumption that plastic deformation produces a new state, characterized by a higher T_c , the normal effect of all-sided compression which lowers T_c is superposed on that change of state. For Tl, it must be assumed that plastically deformed Tl has a normal sign of $\Delta T_c/\Delta P$, and this is confirmed for $r > 12$. It is possible that under the conditions of these expts. Tl has undergone the polymorphous transition Tl II \rightarrow Tl III (Braggman, C.A. 30, 919, 3705). An indication that these processes are not merely the result of an accumulation of phys. defects is seen in the fact that the width of the range of the superconductive transition, which as a function of r increases through a max. for Sn, increases linearly in the case of Hg.

Title : Effect of Inhomogeneous Elastic Deformation on Superconductivity

Orig Pub : Uch. zap. Leningovsk. un-t, 1958, 64, 153--157

Abstract : An investigation was made of the change of the superconducting properties of Sn and Tl as a result of inhomogeneous elastic and elastic-plastic deformation (twisting and compression). The twisting was carried out by stretching spirals (6 mm in diameter) made of wire of the investigated metals (of diameters 0.25 and 0.5 mm respectively) at helium temperature. To produce compression, specimens in the form of tin wires 1.1 -- 0.2 mm in diameter and approximately 30 mm long were compressed between glass plates. Curves are given to illustrate the effects of the deformation. Analysis of the results leads the authors to the conclusion that the shift in the critical temperature T_c under the action of inhomogeneous elastic deformation is determined by the portions of the specimen under

AUTHORS: Golik, V.R., Sirenko, G.A. and Khotkevich, V.I.
TITLE: X-ray Study of Deformation of Metal Crystal Lattices.
Deformed at Low Temperatures
PERIODICAL: Fizika metallov i metallovedeniye, 1959, Vol 8, Nr 2,
pp 235 - 239 (USSR)
ABSTRACT: Deformation at 77 °K of commercially pure iron and
aluminium and spectrographically pure lead was studied.
The specimens were initially free from distortion and
were deformed by uni-axial compression at both room
temperature and temperature of liquid nitrogen. The
latter samples were investigated in a low-temperature
X-ray chamber (Figure 1). The specimen was partly
immersed and also sprayed by liquid nitrogen, giving a
variation of less than $\pm 0.2^\circ$. An approximate method
(B. Ya. Pines - Ref 3) was used to distinguish between
the effects of "fine dispersion" and "micro-distortion".
Figure 3 shows that even at small deformations (2-5%)
a fine dispersion is developed with coherent regions of
approximately 10^{-5} cm. With greater deformation these

Card1/3

SOV/1964-8-2-12/26

X-ray Study of Deformation of Metal Crystal Lattices, Deformed at Low Temperatures

regions increase in size by 2-5 times. Figures 4 and 5 show the relation between micro-deformations and distance for aluminium and armco iron. Similar curves were obtained for lead. These show that the main effect of distortion of the crystal lattice is obtained at the very beginning of deformation. Deformation at low temperatures produces more micro-distortion than at room temperature. Curves of relative micro-deformation at low temperature are shown in Figure 6. These show it is inhomogeneous and passes through a maximum. This maximum increases with increasing deformation and decreasing temperature. Micro-stresses in the samples were calculated and an attempt was made to relate them to creep limit. It was shown that the micro-stresses are always less than the creep limit. Figure 7 shows that a linear relationship exists between the micro-deformation of the lattice and the creep limit. A similar relationship occurs with

Card 2/5

SOV/126-3-2-12/26

X-ray Study of Deformation of Metal Crystal Lattices, Deformed at Low Temperatures

hardness. From the obtained data, the mean values of the elastic energy of deformation were calculated. With 50% deformation at 77 °K there are 0.02, 0.09 and 0.34 cal/mol for lead, aluminium and iron, respectively. These values are only small percentages of the total latent energies of deformation. There are 7 figures and 14 references, of which 10 are Soviet and 4 English.

TITLE: Influence of Vanadium on Phase Transformations in
Manganese Steel

PERIODICAL: Fizika metallov i metallovedeniye, 1960, Vol.10, No.5,
pp.786-790

TEXT: The authors give results of a study of the influence of vanadium on the kinetics of the decomposition of the solid solution, carbide formation and solution of vanadium carbides in manganese steel. Three types of steel with about 0.15% C and 1.5% Mn were used: type $\Phi 57$ (F57) had a vanadium content of 0.57%, corresponding to the stoichiometric composition of vanadium carbide; $\Phi 11$ (F11) corresponding to that in production heats (0.11% V); and the third type $\Phi 0$ (F0) had no vanadium. Blanks (20 x 20 x 8 mm bars and 8 x 80 mm cylinders) from hot-rolled strip were cut along the direction of rolling and hardened from 1200°C in water at 4°C. The blanks were then reheated to 100 to 1200°C, again quenched and cut into specimens, from which the

TITLE: Low-temperature^γ X-Ray Chamber^γ

PERIODICAL: Zavodskaya laboratoriya, 1960, Vol 36, Nr 3, pp 364-365 (USSR)

TEXT: An X-ray chamber which permits investigations of massive metal samples (deformed at -196°) with constant temperature after deformation and during exposure being secured was designed (Fig 1). In the chamber, provision is made for cooling with liquid nitrogen with only the lower part of the sample being immersed in nitrogen. The sample can be turned and is cooled by nitrogen flowing over it. The application of a sharply focusing X-ray tube and the large surface of the sample irradiated make it possible to obtain a considerable reduction of the time of exposure. The photometric curves obtained with a deformed and nondeformed iron sample are given as an example (Fig 2). There are 2 figures and 1 Soviet reference.

TITLE: Microfractographic study of steel fractures depending on the destruction temperature

PERIODICAL: Referativnyy zhurnal. Metallurgiya, no. 1, 1962, 32 - 33, abstract 11217 (Sb. tr. Ukr. n.-l. in-t metallor, no. 7, 1961, 199 - 205)

TEXT: By the electronic microscopy method (by investigating titanium imprints with 3M-3 (EM-3) electronic microscope) the fracture of Menazhe samples made of normalized MCt3 (MSt3) steel destructed at temperatures from +90°C to -196°C were studied. On the basis of microfractographic study of the microstructure of fractures depending on the testing temperature, a criterion for the disposition of steel to the brittle destruction is suggested. The fractures are classified into the "semibrittle" ones (with a "wavy pattern") and the "brittle proper" ones (with "tongues"). There are 11 references. ✓

TITLE: Solution and formation of niobium carbide in low-
carbon manganese steel

PERIODICAL: Fizika metallov i metallovedeniye, v.14, no.4, 1962,
555-558

TEXT: The temperature of solution of niobium carbide in low-carbon manganese steel, as well as the rejection of a special carbide during tempering, was investigated for several heats produced in a 250 kg induction furnace with a basic crucible. Composition (wt.%): 0.16/0.15 C, 0.75/1.28 Mn, 0.26/0.29 Si, 0.036/0.050 S, 0.020 P and 0.06-0.29 Nb. The produced 65 kg ingots were rolled into 11 x 70 mm strip from which 80 x 5.5 mm cylindrical and 10 x 10 x 5 mm polished specimens were cut in the longitudinal direction. The carbide transformations were studied by electron diffraction (reflection method) by measuring the electric resistivity (accuracy $\pm 1.5\%$), the coercive force (ballistically, accuracy $\pm 1\%$) and the Vickers hardness on specimens in the following states: hardened in water from 600, 700, Card 1/3

Solution and formation of ...

S/126/62/014/004/011/017
E073/E535

800, 900, 1000, 1100 and 1200°C; hardened from 1200°C followed by annealing for three hours in the temperature range 200-600°C (in steps of 100°C). Niobium carbide was found to dissolve above 1100°C; steels with equal Nb contents but higher Mn contents showed a sharp rise in the coercive force for hardening temperatures in the range of 900-1200°C. This indicates that an increased Mn content in the steel brings about dissolution of the carbide phase associated with a special carbide. In all the investigated steels the decomposition of the solid solution began at tempering temperatures above 200°C, whereby iron carbide formed first and then, at higher tempering temperatures (400°C for the steel containing 28% Mn and 600°C for steel with 0.75% Mn), niobium carbide began to form. With increasing tempering temperatures the coercive force decreased and, due to the effect of Nb carbide formation, the decrease in the range 400-600°C was less for Nb-containing steel than for Nb-free steels. The change in hardness in the tempering temperature range 400-500°C is similar to the change in coercive force; addition of Nb impedes the drop in hardness and at 600°C there was even a slight increase in hardness. There are 3 figures and 2 tables.

Title: Fine structure of brittle fractures

Annotation: Metallovedeniye i termicheskaya obrabotka metallov,
no.5, 1962, 40-42 + 1 plate

Summary: Commercial high-purity iron, the stainless steels
7 (X80) 3, 15, 210 (G10) and a low alloy steel (0.18% C,
1.30% Mn, 0.27% Si, 0.10% V, 0.040% Ti and 0.030% S) were subjected
to impact tests in the temperature range +150 to -195°C and the
fractures were studied by means of an electron microscope using
two-stage carbon replicas. Furthermore, the cleavage planes of
single crystals of zinc, bismuth and antimony, fractured at 20°C,
were studied by means of an optical microscope. It was found
that the foci of systems of cracks formed on imperfections of the
crystal lattice (grain boundaries and fragments) including those
due to plastic deformation prior to failure. Fractograms also
showed systems of cracks which, after extending within the limits
of the cleavage plane, showed bends at boundaries with adjacent
fragments. Formation of cracks during brittle failure can also
Card 1/3

Fine structure of brittle fractures

S/129/52/035/005/007/011
E073/E535

be due to various macro- and micro-nonuniformities. Some microphotographs of admixture-contaminated materials showed cracks at the spots where these admixtures were distributed. Low temperature (-100, -196°C) cleavages showed little, oriented mounds and it is assumed that these represent local tearing out of metal in the neighbourhood of the nonuniformities. Their appearance can be explained by the macro characteristics of the stalled fractures; their appearance on micro-photographs corresponds with a bend in the curve representing the load-angle versus temperature. It is therefore assumed that the appearance of mounds is due to a sharp drop in the plasticity of metal prior to fracture, and their presence on micro-photographs of cleavage planes is an indication that the material is in the brittle state. Apparently, this indication is general and applies also to other cold short metals and alloys. Cleavage planes with a terrace-like system of cracks in the form of parallel ridges are characteristic of mixed fractures and are the result of "semi-brittle" fracture caused by considerable plastic deformation.

Card 2/3

Structure of brittle fractures S/129/11/001/001/001/001

of failure, whilst cleavage planes with developed
microvoids seem to characterize brittle fracture. These
are figures.

3

ACCESSION NR: AR5000596

The cleavability of single crystals of zinc[?], bismuth[?], and tin[?] fractured at +20° was also studied with an optical microscope. It is shown that brittle fracture arises at the locations of macro and micro non-homogeneities and of various imperfections in the crystal lattice (grain boundaries and lines of cleavage of fragments within the limits of individual crystals). Brittle fracture is accompanied by plastic deformation which, depending on temperature of fracture and orientation of the individual crystals, can take place either by fragmentation or by twinning. The effect of work hardening of the samples before brittle fracture is superimposed on the effect of plastic flow, which accompanies the slip and manifests itself in various changes in the thin structure parts of the fractures. 7 literature titles. TITLE: Rate of flotation. (Skorost' flotatsii)

PERIODICAL: Tsvetnyye Metally, 1957, no.2, pp. 8 - 14 (USSR)

ABSTRACT: In spite of the considerable amount of work it has attracted, the question of the kinetics of flotation remains unsolved. The author critically considers the treatments of flotation kinetics by Krokain [Ref. 1], Klassen and Berger [Ref. 2] and by Beloglazov [Ref. 3]. He presents in tabular and graphical form results of his experiments (carried out under the direction of I.A. Kakovskiy and V.K. Batak) on rates of flotation of cerussite. The data (showing the kinetics of the process) relate to various sodium sulfide consumptions, and curves for finding the values of constants in the equations are also given. The author concludes that generally accepted truths as well as experimental data must be taken into account if useful results are to be obtained. He decides that the rate of flotation is constant when there is insufficient liquid - gas surface but becomes a function of time and of rate of flotation when there is an excess of surface. The author's final conclusion that the flotation rate equation can be used to choose flotation conditions without experiment is criticised in an editorial note.

Senior Engineer

TITLE: Useful Textbook (Poleznoye posobiye)

PERIODICAL: Neftyanik, 1959, Nr 3, p 35 (USSR)

ABSTRACT: The authors state that among numerous books and pamphlets recently published by the Gostoptekhnizdat, the textbook entitled "General Overhauling of Oil and Gas Wells" is worth serious attention. In his work the author presents material of considerable importance and interest for personnel specializing in the overhaul of subterranean well equipment. A chapter of this book is devoted to a description of photographic, acoustic and electrical methods which make possible a comprehensive study of oil wells. These methods have never been discussed in Soviet domestic literature. In another chapter the author reviews existing systems of packers manufactured in the Soviet Union and in foreign

Useful Textbook

507/52-59-3-42/44

countries. This will help engineers to select the most suitable packer. Fishing tools and operations are also dealt with in detail. This valuable book has, however, certain shortcomings. Instead of presenting designs of equipment, the author provides only sketches. Certain operations such as the exclusion of bottom waters are not as fully described as they might be. Nevertheless, there is no doubt that this useful book will be read with considerable interest by oilmen.

Title : Some Facts and Bases in Selecting Native Components for Newly Introduced Varieties

Orig Pub: Izv. Moldav. fil. AN SSSR, 1954, No 6, 85-89

Abstract: It is emphasized that the problem of choosing native components for woody varieties newly introduced in forestry has been poorly studied in theory as well as in practice. The fast-growing foreign varieties often diminish their growth tempo in new environments and remain under a canopy of their native variety companions. Under conditions of new surroundings, plants often behave in a totally different manner than in their native land, and even produce new forms. Certain conditions are necessary for foreign varieties transposed suddenly into more severe circumstances.

J-3

Abs Jour: Referat Zh-Biol., No 6, 1957, 22559

Accordingly, conditions for their growth should be chosen which are nearest to corresponding natures of foreign plants, and a high level of agricultural technique should be present. In mixing them with the native ones, the following conditions should be observed: To secure a considerable quantitative preponderance of the introduced variety over native woody varieties; to avoid introduction into cultivation of first magnitude trees when the foreign varieties are represented by trees of first magnitude. To choose the component varieties for newly introduced varieties with a view toward creating advantageous growth conditions: shading and improving the soil, accumulation of winter precipitations, etc. The economic value of serviceable varieties is determined mainly by the basic newly-introduced variety.

Title : An Experiment in the Fall Planting of Eucornia

Orig Pub : Lesn. kh-vo, 1957, No 6, 82.

Abstract : A comparison of the spring planting of 1955 and the fall one of 1954 which was made in the Dnestr River flood-land has shown that it is most expedient to plant eucornia in the late autumn period, provided there is enough humidity present at that time. Root formation occurs best in the seedlings with complete foliage left on them. The sign that the seedlings are ready for transplanting appears as the turning brown of two to five bottom leaves which crumble at a mere touch.

TITLE: A stamping device for producing corrugated filter disks from conical blanks.
Class 511, No. 173600

SOURCE: Byulleten' izobreteniy i tovarnykh znakov, no. 15, 1965, 144

TOPIC TAGS: pneumatic device, metal stamping, filter

ABSTRACT: This Author Certificate presents a stamping device for producing corrugated filter disks from conical blanks. The device contains a piston (placed in a pneumatic chamber and driven by a pneumatic cylinder) and a die (see Fig. 1 on the Enclosure). To improve the quality and efficiency of filters, the piston is made of concentric rings mounted on movable disks. Orig. art. has: 1 figure.
